Field of the Invention The present invention relates to an electric compressor. In particular, it relates to a vibration-proofing structure of a gear-driven electric compressor or to a shock-absorbing structure of the electric compressor. 2. Description of the Related Art Generally, a compression mechanism of a known electric compressor includes a motor, a motor housing, a cylinder block, a cylinder, an eccentric shaft, a centrifugal clutch, a crankshaft and a shaft tube. The cylinder block is rotatably supported by a shaft tube via the eccentric shaft, so that the eccentric shaft is movable radially with respect to the shaft tube. The eccentric shaft is rotated by the motor, while being rotated by the crankshaft via the centrifugal clutch which is held in an engaged state. The crankshaft is connected with a piston disposed in the cylinder, so that the piston is rotated by the rotation of the crankshaft. The crankshaft is supported by the shaft tube via a bearing provided thereon. The bearing is retained in a lubricant, which is filled in a bearing chamber which is formed adjacent to the bearing and has an opening provided at a distal end of the shaft tube. A lubricant tank is located at a position where the opening of the bearing chamber is in communication with the outside. With the above construction, if an external force is applied to the shaft tube, the lubricant in the lubricant tank is forced to leak through the opening of the bearing chamber, which results in lubrication failure. As a result, the bearing is abraded and vibrates as it rotates, which causes unsmooth rotation of the crankshaft. The invention was developed in view of the above problem, and an ba244e880a
