We are using site-directed mutagenesis, various optical techniques, electron microscopy and biochemical methods to study the two subunits, the alpha and beta subunits, of the enzyme. A three-dimensional model of the enzyme has been developed from electron microscopy images. We are also developing techniques to study the distribution of the enzyme within the bacterial cell. Although this enzyme is essential for the bacterial cell, very little is known about its structure and function. This enzyme, together with the membranes that surround it, constitute the bacterial F0F1 ATPase enzyme that produces the electrochemical proton gradient that drives synthesis of ATP by the F1 ATPase. The F0F1 ATPase has been suggested to be a potential chemotherapeutic target for the treatment of multidrug-resistant bacterial infections. A novel system for expression of proteins in the entire proteome of E. coli has recently been developed in our laboratory. We have expressed the E. coli F0F1 ATPase subunits and are using them in biochemical, electron microscopy and optical 3ef4e8ef8d
